

## **1. Suppose you're a web developer in a company and need to decide if you'll use vanilla (plain) Python for a project, or a framework like Django instead. What are the advantages and drawbacks of each?**

Using plain Python gives you full control over how everything is built, which can be helpful for small projects or scripts. However, building a full web app from scratch would take much longer because you'd have to handle routing, database connections, security, and more on your own.

Using Django makes development much faster because it already includes tools for handling databases, authentication, and security. The downside is that it has a specific structure you need to follow, which can feel restrictive if you want to design everything your own way.

## **2. In your own words, what is the most significant advantage of Model View Template (MVT) architecture over Model View Controller (MVC) architecture?**

The biggest advantage of MVT is that Django handles a lot of the control logic for you. This makes development simpler because you mainly focus on the data (models), the logic (views), and how it looks (templates). It reduces setup work and keeps projects organized.

## **3. Three goals for this Achievement**

1. I want to understand how all parts of a Django project work together, especially models, views, templates, and URLs.
2. I want to get comfortable using Django's ORM and working with databases.
3. By the end of this Achievement, I want to be confident building a full web application using Django.
